Areman Hashemi

Most of my work was implementing backend support for the different main pages. Since I was unfamiliar with swift I didn't make the initial time to learn the testing framework so everything was done by hand and with print statements. Between chores, groceries, and bills my testing was mostly of the same pattern. I would print the snapshot results of querying the db, and look at the firebase console to see how adding values to the DB were stored. Since a big part of my task was having synchronization between different users another major part of my testing was running two instances of the app between housemates and adding | deleting | modifying db values to see how the two apps interacted. One major way this fails is that I wasn't able to see interactions between a large number of users at the same time.
